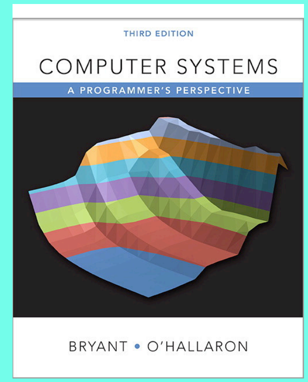
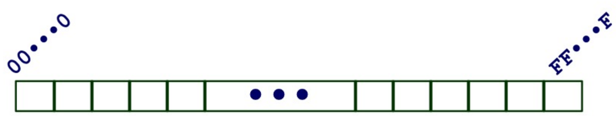
- Computer Systems (Bryant and O'Hallaron)
  - A Programmer's Perspective



Byte-Oriented Memory Organization



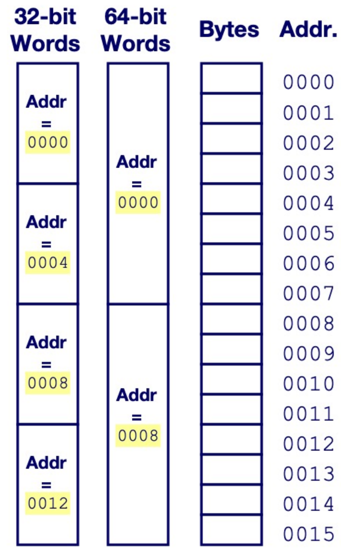
- **Programs refer to data by address**
  - Imagine all of RAM as an enormous array of bytes
  - An address is an index into that array
    - A pointer variable stores an address
- **System provides a private *address space* to each "process"**
  - A process is an instance of a program, being executed
  - An address space is one of those enormous arrays of bytes
  - Each program can see only its own code and data within its enormous array
  - We'll come back to this later ("virtual memory" classes)

Machine Words

- **Any given computer has a "Word Size"**
  - Nominal size of integer-valued data
    - and of addresses
  - Until recently, most machines used 32 bits (4 bytes) as word size
    - Limits addresses to 4GB (2^{32} bytes)
  - Increasingly, machines have 64-bit word size
    - Potentially, could have 18 EB (exabytes) of addressable memory
    - That's 18.4 X 10^{18}
  - Machines still support multiple data formats
    - Fractions or multiples of word size
    - Always integral number of bytes

Addresses *Always* Specify Byte Locations

- Address of a word is address of the first byte in the word
- Addresses of successive words differ by 4 (32-bit) or 8 (64-bit)

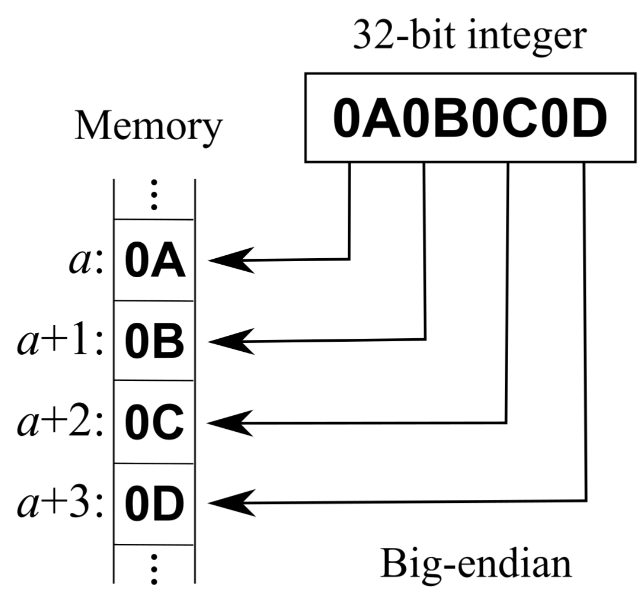


Example Data Representations

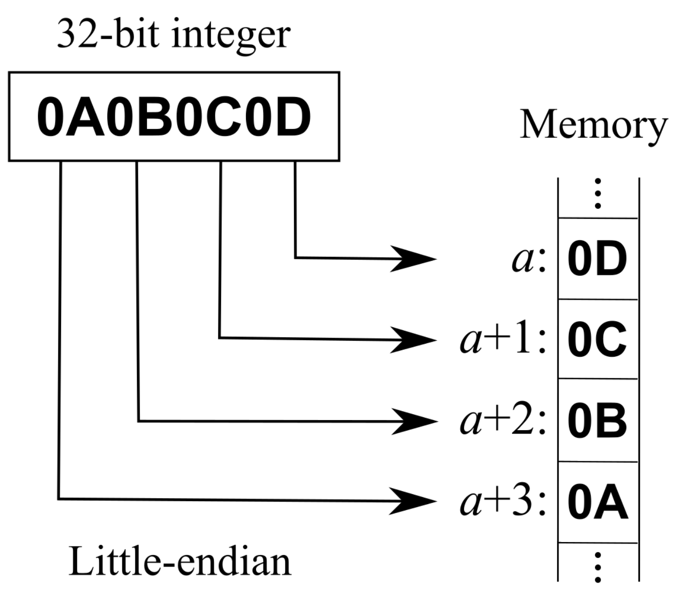
C Data Type	Typical 32-bit	Typical 64-bit	x86-64
`char`	1	1	1
`short`	2	2	2
`int`	4	4	4
`long`	4	8	8
`float`	4	4	4
`double`	8	8	8
pointer	4	8	8

Byte Ordering

- So, how are the bytes within a multi-byte word ordered in memory?
- Conventions
  - Big Endian: Sun, PPC Mac, *network packet headers*
    - Least significant byte has highest address
  - Little Endian: *x86*, ARM processors running Android, iOS, and Windows
    - Least significant byte has lowest address



https://en.wikipedia.org/wiki/Endianness



https://en.wikipedia.org/wiki/Endianness

Byte Ordering Example

Example
- Variable x has 4-byte value of 0x01234567
- Address given by &x is 0x100

Big Endian

		0x100	0x101	0x102	0x103		
		01	23	45	67		

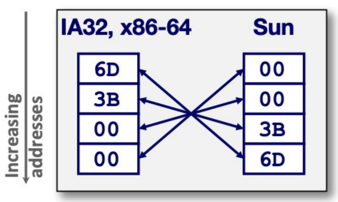
Little Endian

		0x100	0x101	0x102	0x103		
		67	45	23	01		

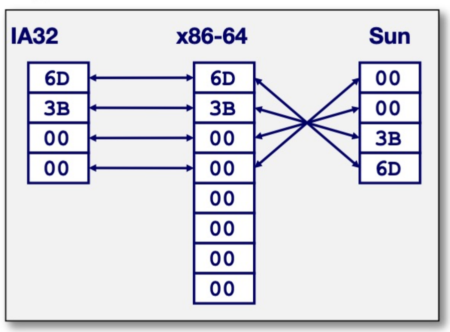
Representing Integers

Decimal:	15213			
Binary:	0011	1011	0110	1101
Hex:	3	B	6	D

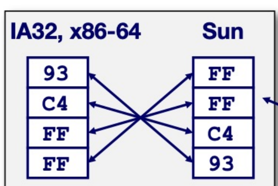
`int A = 15213;`



`long int C = 15213;`



`int B = -15213;`



Two's complement representation

Examining Data Representations

Code to Print Byte Representation of Data
- Casting pointer to unsigned char * allows treatment as a byte array

```
typedef unsigned char *pointer;

void show_bytes(pointer start, size_t len){
  size_t i;
  for (i = 0; i < len; i++)
    printf("%p\t0x%.2x\n",start+i, start[i]);
  printf("\n");
}
```

Printf directives:
%p: Print pointer
%x: Print Hexadecimal

`show_bytes` Execution Example

```
int a = 15213;
printf("int a = 15213;\n");
show_bytes((pointer) &a, sizeof(int));
```

Result (Linux x86-64):

```
int a = 15213;
0x7fffb7f71dbc    6d
0x7fffb7f71dbd    3b
0x7fffb7f71dbe    00
0x7fffb7f71dbf    00
```

Representing Pointers

```
int B = -15213;
int *P = &B;
```

Sun	IA32	x86-64
EF	AC	3C
FF	28	1B
FB	F5	FE
2C	FF	82
		FD
		7F
		00
		00

Different compilers & machines assign different locations to objects

Even get different results each time run program

Representing Strings

```
char S[6] = "18213";
```

- **Strings in C**
  - Represented by array of characters
  - Each character encoded in ASCII format
    - Standard 7-bit encoding of character set
    - Character "0" has code 0x30
      - Digit *i* has code 0x30+*i*
  - String should be null-terminated
    - Final character = 0
- **Compatibility**
  - Byte ordering not an issue

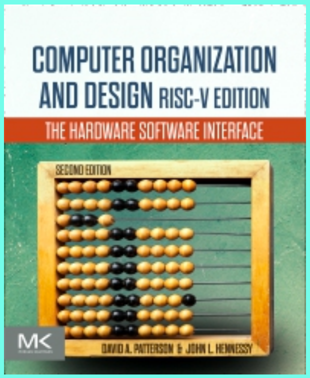
  - The Hardware/Software Interface



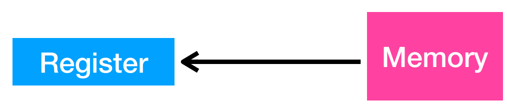
Memory operands

Data transfer instructions

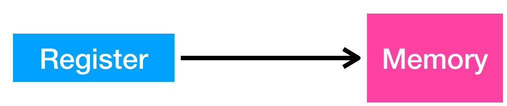
- Main memory used for composite data
  - arrays, structures, dynamic data
- Register <-> Memory instructions
  - **load** values from memory into registers
  - **store** result from register to memory
- Memory is **byte addressed**
  - each address identifies an 8-bit byte
  - RISC-V is **Little Endian**
  - RISC-V and x86 do not require words to be **aligned** in memory
    - alignment restriction forces **words** to start at addresses that are multiples of the word size

Fetching and storing data

- Values can be fetched from memory
  - using a `load` instruction



- Values can be stored in memory
  - using a `store` instruction



Load instructions

- Load **word** from memory

destination register   source address

```
lw  x9,  32(x22)
```

- destination can be any register
- source address uses a constant (**offset**) added to the register value (**base**)

Store instruction

- Store **word** into memory

source register   destination address

```
sw  x9,  48(x22)
```

- source can be any register
- destination address uses a constant (**offset**) added to the register value (**base**)

Example with memory operand

- C code

```
g = h + A[8];
```

- Compiled RISC-V code
  - index 8 requires offset of 32 (4 bytes)

```
# assume g in x21, h in x22
# assume base address of A in x23
lw      x21, 32(x23)
add     x21, x21, x22
```

Example with memory operand

- C code

```
A[7] = h + A[5];
```

- Compiled RISC-V code
  - try yourself (assume h in x21 and base address of A in x22)

```
lw      x9, 20(x22)
add     x9, x21, x9
sw      x9, 28(x22)
```

Registers vs memory

- Operating on memory data requires **loads** and **stores**
  - consider memory latency and additional instructions to be executed
- **Registers** are a fast read/write memory right on the CPU that can hold values
- Compiler must use registers for variables as much as possible
  - only spill to memory for less frequently used variables
  - **register optimization** is important!
